# GameFusion

**1. Project Overview**

This project is a game selector application built using Python and the Pygame library. It offers a user interface for selecting between two games: **Snake** and **Tic-Tac-Toe**. The application incorporates **Text-to-Speech (TTS)** functionality using the pyttsx3 library to enhance accessibility by announcing key events like game start, win, or loss. It provides an interactive way for players to choose and play games, and also includes options to restart or quit the games.

**2. Technologies Used**

- **Python 3.x**: The primary programming language used for this project.
- **Pygame**: A library used to build the graphical user interface (GUI) and manage the game's logic, rendering, and events.
- **pyttsx3**: A text-to-speech library used to provide speech output for important game events.
- **Threading**: To run the TTS engine in a separate thread, allowing it to work asynchronously without blocking the main game loop.

**3. Game Selector Interface**

The game selector serves as the main entry point for the project. It presents a menu with two buttons:

- **Play Snake Game**
- **Play Tic-Tac-Toe**

When a player clicks on either button, the respective game starts, and the TTS engine announces the selection.

**Key Features:**

- **Graphical Interface**: A simple, clean interface with buttons centred on the screen.
- **Text-to-Speech**: Upon loading the game selector, the app welcomes the player with a speech prompt.
- **Mouse Interaction**: The user selects a game by clicking on the respective button.
- **Game Transition**: Once a game is chosen, the selector exits, and the corresponding game starts.

**4. Snake Game**

The Snake game is a classic game where the player controls a snake to eat food, which increases its size. The goal is to avoid hitting the snake's body or the screen borders.

**Key Features:**

- **Movement**: The player controls the snake using the arrow keys.
- **Food and Growth**: The snake eats food items (red blocks) that spawn randomly on the screen. Each time the snake eats, it grows longer.

- **Game Over Condition**: The game ends if the snake hits the boundaries of the screen or runs into itself.
- **Score System**: The player's score is displayed at the top left corner of the screen, and it increases with each food item eaten.
- **Restart/Exit**: Upon game over, the user is prompted to either play again or quit the game.

**Text-to-Speech Integration:**

- The TTS engine announces the score after the game ends and provides feedback like "Game Over" or "You won!" based on the outcome.

**5. Tic-Tac-Toe**

The Tic-Tac-Toe game allows two players to play on a 3x3 grid. Players alternate placing 'X' and 'O' on the grid with the objective of getting three of their marks in a row, either horizontally, vertically, or diagonally.

**Key Features:**

- **Grid and Turn System**: The board is divided into 9 cells, and players click on an empty cell to place their mark. The game alternates turns between 'X' and 'O'.
- **Winning and Tying**: The game checks for a winner after every move. If all cells are filled without a winner, the game ends in a tie.
- **Player Names**: Before starting the game, players are asked to input their names.
- **Restart/Exit**: Once the game ends, the user can choose to play again or quit.

**Text-to-Speech Integration:**

- The TTS engine announces the current player's turn, the winner, or the tie situation.

**6. Game Loop and Event Handling**

Both games—Snake and Tic-Tac-Toe—feature a main game loop that:

- **Processes User Input**: The game waits for mouse or keyboard input (clicks or key presses).
- **Updates Game State**: Based on the user's actions, the game's state (e.g., snake position, board updates) is modified.
- **Renders the Graphics**: The Pygame library handles drawing the game elements (e.g., snake, grid, food) and updating the screen after each action.
- **End Conditions**: Each game checks for conditions that would end the game (e.g., the snake colliding with itself or the board being full).

**7. Text-to-Speech (TTS) Integration**

The **pyttsx3** library is used for text-to-speech functionality throughout the project. The TTS engine announces important messages:

- **Game start and end messages**: "Starting Snake Game," "Game Over," "You won!"
- **Score updates**: The score of the Snake game is announced after every significant event.

Threading is used to handle the TTS functionality in parallel with the game loops, ensuring that the speech output doesn't block the main game flow.

**8. Project Structure**

The project is structured with separate files for the game logic and the game selector:

- **game_selector.py**: Manages the game selection interface and handles the transition to either the Snake game or Tic-Tac-Toe.
- **snake.py**: Contains the logic for the Snake game, including movement, collision detection, and score management.
- **tictacto.py**: Contains the logic for Tic-Tac-Toe, including board rendering, checking for a winner, and player input handling.

**9. Challenges Faced**

- **Handling Concurrent Speech and Game Logic**: Ensuring that TTS runs smoothly without interrupting or delaying the main game loop was a challenge. This was addressed by using threading.
- **Event Handling for Tic-Tac-Toe**: The game had to manage mouse clicks effectively to register player moves and check for win conditions after each move.
- **Game Reset Mechanism**: Implementing a smooth restart mechanism for both games after they end required careful management of game state and UI updates.

**10. Future Improvements**

- **Enhanced Graphics**: The visuals for both games could be enhanced with better assets, animations, and sound effects.
- **Additional Games**: Other classic games such as Pong, Chess, or Minesweeper could be added to the selector for variety.
- **Multiplayer Support**: Allowing multiplayer functionality over a network could enhance the Tic-Tac-Toe game.
- **Sound Effects**: Adding sound effects for actions like placing a move in Tic-Tac-Toe or eating food in Snake would improve user experience.

**11. Conclusion**

This project successfully integrates multiple Python libraries (Pygame, pyttsx3, and threading) to create an interactive game selector application. It provides a fun and engaging way to play two classic games, Snake and Tic-Tac-Toe, while leveraging accessibility features like text-to-speech. The modular structure of the project allows for easy extension and the addition of new games or features in the future.
